pathlib — Object-oriented filesystem paths

New in version 3.4.

Source code: Lib/pathlib.py

This module offers classes representing filesystem paths with semantics appropriate for different operating systems. Path classes are divided between pure paths, which provide purely computational operations without I/O, and concrete paths, which inherit from pure paths but also provide I/O operations.

If you've never used this module before or just aren't sure which class is right for your task, Path is most likely what you need. It instantiates a concrete path for the platform the code is running on.

Pure paths are useful in some special cases; for example:

- 1. If you want to manipulate Windows paths on a Unix machine (or vice versa). You cannot instantiate a WindowsPath when running on Unix, but you can instantiate PureWindowsPath.
- 2. You want to make sure that your code only manipulates paths without actually accessing the OS. In this case, instantiating one of the pure classes may be useful since those simply don't have any OS-accessing operations.

See also

PEP 428: The pathlib module – object-oriented filesystem paths.

See also

For low-level path manipulation on strings, you can also use the os.path module.

Basic use

Importing the main class:

```
>>> from pathlib import Path
```

Listing subdirectories:

```
>>>
>>> p = Path('.')
>>> [x for x in p.iterdir() if x.is_dir()]
[PosixPath('.hg'), PosixPath('docs'), PosixPath('dist'),
   PosixPath('__pycache__'), PosixPath('build')]
```

Listing Python source files in this directory tree:

```
>>> list(p.glob('**/*.py'))
[PosixPath('test_pathlib.py'), PosixPath('setup.py'),
   PosixPath('pathlib.py'), PosixPath('docs/conf.py'),
   PosixPath('build/lib/pathlib.py')]
```

Navigating inside a directory tree:

```
>>>
>>>
>>> p = Path('/etc')
>>> q = p / 'init.d' / 'reboot'
>>> q
PosixPath('/etc/init.d/reboot')
>>> q.resolve()
PosixPath('/etc/rc.d/init.d/halt')
```

Querying path properties:

```
>>> q.exists()
True
>>> q.is_dir()
```

```
False
```

Opening a file:

```
>>>
>>> with q.open() as f: f.readline()
...
'#!/bin/bash\n'
```

Pure paths

Pure path objects provide path-handling operations which don't actually access a filesystem. There are three ways to access these classes, which we also call *flavours*:

```
class pathlib.PurePath(*pathsegments)
```

A generic class that represents the system's path flavour (instantiating it creates either a PurePosixPath or a PureWindowsPath):

```
>>> PurePath('setup.py') # Running on a Unix machine
PurePosixPath('setup.py')
```

Each element of *pathsegments* can be either a string representing a path segment, an object implementing the os.PathLike interface which returns a string, or another path object:

```
>>> PurePath('foo', 'some/path', 'bar')
PurePosixPath('foo/some/path/bar')
>>> PurePath(Path('foo'), Path('bar'))
PurePosixPath('foo/bar')
```

When *pathsegments* is empty, the current directory is assumed:

```
>>> PurePath()
PurePosixPath('.')
```

When several absolute paths are given, the last is taken as an anchor (mimicking os.path.join()'s behaviour):

```
>>> PurePath('/etc', '/usr', 'lib64')
PurePosixPath('/usr/lib64')
```

```
>>> PureWindowsPath('c:/Windows', 'd:bar')
PureWindowsPath('d:bar')
```

However, in a Windows path, changing the local root doesn't discard the previous drive setting:

```
>>> PureWindowsPath('c:/Windows', '/Program Files')
PureWindowsPath('c:/Program Files')
```

Spurious slashes and single dots are collapsed, but double dots ('..') are not, since this would change the meaning of a path in the face of symbolic links:

```
>>>
>>> PurePath('foo//bar')
PurePosixPath('foo/bar')
>>> PurePath('foo/./bar')
PurePosixPath('foo/bar')
>>> PurePath('foo/../bar')
PurePosixPath('foo/../bar')
```

(a naïve approach would make PurePosixPath('foo/../bar') equivalent to PurePosixPath('bar'), which is wrong if foo is a symbolic link to another directory)

Pure path objects implement the os.PathLike interface, allowing them to be used anywhere the interface is accepted.

Changed in version 3.6: Added support for the os.PathLike interface.

```
class pathlib.PurePosixPath(*pathsegments)
```

A subclass of PurePath, this path flavour represents non-Windows filesystem paths:

```
>>> PurePosixPath('/etc')
PurePosixPath('/etc')
```

pathsegments is specified similarly to PurePath.

```
class pathlib.PureWindowsPath(*pathsegments)
```

A subclass of PurePath, this path flavour represents Windows filesystem paths:

```
>>>
```

```
>>> PureWindowsPath('c:/Program Files/')
PureWindowsPath('c:/Program Files')
```

pathsegments is specified similarly to PurePath.

Regardless of the system you're running on, you can instantiate all of these classes, since they don't provide any operation that does system calls.

General properties

Paths are immutable and hashable. Paths of a same flavour are comparable and orderable. These properties respect the flavour's case-folding semantics:

```
>>>
>>> PurePosixPath('foo') == PurePosixPath('F00')
False
>>> PureWindowsPath('foo') == PureWindowsPath('F00')
True
>>> PureWindowsPath('F00') in { PureWindowsPath('foo') }
True
>>> PureWindowsPath('C:') < PureWindowsPath('d:')
True</pre>
```

Paths of a different flavour compare unequal and cannot be ordered:

```
>>>
>>> PureWindowsPath('foo') == PurePosixPath('foo')
False
>>> PureWindowsPath('foo') < PurePosixPath('foo')
Traceback (most recent call last):
   File "<stdin>", line 1, in <module>
TypeError: '<' not supported between instances of 'PureWindowsPath'
and 'PurePosixPath'</pre>
```

Operators

The slash operator helps create child paths, similarly to os.path.join():

```
>>>
>>> p = PurePath('/etc')
>>> p
PurePosixPath('/etc')
>>> p / 'init.d' / 'apache2'
PurePosixPath('/etc/init.d/apache2')
>>> q = PurePath('bin')
```

```
>>> '/usr' / q
PurePosixPath('/usr/bin')
```

A path object can be used anywhere an object implementing os.PathLike is accepted:

```
>>>
>>> import os
>>> p = PurePath('/etc')
>>> os.fspath(p)
'/etc'
```

The string representation of a path is the raw filesystem path itself (in native form, e.g. with backslashes under Windows), which you can pass to any function taking a file path as a string:

```
>>>
>>> p = PurePath('/etc')
>>> str(p)
'/etc'
>>> p = PureWindowsPath('c:/Program Files')
>>> str(p)
'c:\\Program Files'
```

Similarly, calling bytes on a path gives the raw filesystem path as a bytes object, as encoded by os.fsencode():

```
>>> bytes(p)
b'/etc'
```

Note

Calling bytes is only recommended under Unix. Under Windows, the unicode form is the canonical representation of filesystem paths.

Accessing individual parts

To access the individual "parts" (components) of a path, use the following property:

```
PurePath.parts
```

A tuple giving access to the path's various components:

```
>>>
```

```
>>> p = PurePath('/usr/bin/python3')
>>> p.parts
('/', 'usr', 'bin', 'python3')

>>> p = PureWindowsPath('c:/Program Files/PSF')
>>> p.parts
('c:\\', 'Program Files', 'PSF')
```

(note how the drive and local root are regrouped in a single part)

Methods and properties

Pure paths provide the following methods and properties:

PurePath.drive

A string representing the drive letter or name, if any:

```
>>>
>>> PureWindowsPath('c:/Program Files/').drive
'c:'
>>> PureWindowsPath('/Program Files/').drive
''
>>> PurePosixPath('/etc').drive
''
```

UNC shares are also considered drives:

```
>>> PureWindowsPath('//host/share/foo.txt').drive
'\\\host\\share'
```

PurePath.root

A string representing the (local or global) root, if any:

```
>>>
>>> PureWindowsPath('c:/Program Files/').root
'\\'
>>> PureWindowsPath('c:Program Files/').root
''
>>> PurePosixPath('/etc').root
'/'
```

UNC shares always have a root:

```
>>> PureWindowsPath('//host/share').root
'\\'
```

PurePath.anchor

The concatenation of the drive and root:

```
>>>
>>>
PureWindowsPath('c:/Program Files/').anchor
'c:\\'
>>> PureWindowsPath('c:Program Files/').anchor
'c:'
>>> PurePosixPath('/etc').anchor
'/'
>>> PureWindowsPath('//host/share').anchor
'\\\host\\share\\'
```

PurePath.parents

An immutable sequence providing access to the logical ancestors of the path:

```
>>>
>>> p = PureWindowsPath('c:/foo/bar/setup.py')
>>> p.parents[0]
PureWindowsPath('c:/foo/bar')
>>> p.parents[1]
PureWindowsPath('c:/foo')
>>> p.parents[2]
PureWindowsPath('c:/')
```

PurePath.parent

The logical parent of the path:

```
>>>
>>> p = PurePosixPath('/a/b/c/d')
>>> p.parent
PurePosixPath('/a/b/c')
```

You cannot go past an anchor, or empty path:

```
>>>
>>> p = PurePosixPath('/')
>>> p.parent
PurePosixPath('/')
>>> p = PurePosixPath('.')
>>> p.parent
PurePosixPath('.')
```

Note

This is a purely lexical operation, hence the following behaviour:

```
>>> p = PurePosixPath('foo/..')
>>> p.parent
PurePosixPath('foo')
```

If you want to walk an arbitrary filesystem path upwards, it is recommended to first call Path.resolve() so as to resolve symlinks and eliminate ".." components.

```
PurePath.name
```

A string representing the final path component, excluding the drive and root, if any:

```
>>> PurePosixPath('my/library/setup.py').name
'setup.py'
```

UNC drive names are not considered:

```
>>>
>>> PureWindowsPath('//some/share/setup.py').name
'setup.py'
>>> PureWindowsPath('//some/share').name
''
```

PurePath.suffix

The file extension of the final component, if any:

```
>>>
>>> PurePosixPath('my/library/setup.py').suffix
'.py'
>>> PurePosixPath('my/library.tar.gz').suffix
'.gz'
>>> PurePosixPath('my/library').suffix
''
```

PurePath.suffixes

A list of the path's file extensions:

```
>>>
>>> PurePosixPath('my/library.tar.gar').suffixes
['.tar', '.gar']
>>> PurePosixPath('my/library.tar.gz').suffixes
['.tar', '.gz']
>>> PurePosixPath('my/library').suffixes
[]
```

PurePath.stem

The final path component, without its suffix:

```
>>>
>>> PurePosixPath('my/library.tar.gz').stem
'library.tar'
>>> PurePosixPath('my/library.tar').stem
'library'
>>> PurePosixPath('my/library').stem
'library'
```

PurePath.as posix()

Return a string representation of the path with forward slashes (/):

```
>>>
>>> p = PureWindowsPath('c:\\windows')
>>> str(p)
'c:\\windows'
>>> p.as_posix()
'c:/windows'
```

PurePath.as uri()

Represent the path as a file URI. ValueError is raised if the path isn't absolute.

```
>>>
>>> p = PurePosixPath('/etc/passwd')
>>> p.as_uri()
'file:///etc/passwd'
>>> p = PureWindowsPath('c:/Windows')
>>> p.as_uri()
'file:///c:/Windows'
```

PurePath.is absolute()

Return whether the path is absolute or not. A path is considered absolute if it has both a root and (if the flavour allows) a drive:

```
>>>
>>> PurePosixPath('/a/b').is_absolute()
True
>>> PurePosixPath('a/b').is_absolute()
False

>>> PureWindowsPath('c:/a/b').is_absolute()
True
>>> PureWindowsPath('/a/b').is_absolute()
False
>>> PureWindowsPath('c:').is_absolute()
False
>>> PureWindowsPath('c:').is_absolute()
```

True

```
PurePath.is_relative_to(*
other)
```

Return whether or not this path is relative to the *other* path.

```
>>>
>>> p = PurePath('/etc/passwd')
>>> p.is_relative_to('/etc')
True
>>> p.is_relative_to('/usr')
False
```

New in version 3.9.

```
PurePath.is reserved()
```

With PureWindowsPath, return True if the path is considered reserved under Windows, False otherwise. With PurePosixPath, False is always returned.

```
>>>
>>> PureWindowsPath('nul').is_reserved()
True
>>> PurePosixPath('nul').is_reserved()
False
```

File system calls on reserved paths can fail mysteriously or have unintended effects.

```
PurePath.joinpath(*o ther)
```

Calling this method is equivalent to combining the path with each of the *other* arguments in turn:

```
>>>
>>> PurePosixPath('/etc').joinpath('passwd')
PurePosixPath('/etc/passwd')
>>> PurePosixPath('/etc').joinpath(PurePosixPath('passwd'))
PurePosixPath('/etc/passwd')
>>> PurePosixPath('/etc').joinpath('init.d', 'apache2')
PurePosixPath('/etc/init.d/apache2')
>>> PureWindowsPath('c:').joinpath('/Program Files')
PureWindowsPath('c:/Program Files')
```

PurePath.match(pattern)

Match this path against the provided glob-style pattern. Return True if matching is successful, False otherwise.

If *pattern* is relative, the path can be either relative or absolute, and matching is done from the right:

```
>>>
>>> PurePath('a/b.py').match('*.py')
True
>>> PurePath('/a/b/c.py').match('b/*.py')
True
>>> PurePath('/a/b/c.py').match('a/*.py')
False
```

If *pattern* is absolute, the path must be absolute, and the whole path must match:

```
>>>
>>> PurePath('/a.py').match('/*.py')
True
>>> PurePath('a/b.py').match('/*.py')
False
```

As with other methods, case-sensitivity follows platform defaults:

```
>>>
>>>
PurePosixPath('b.py').match('*.PY')
False
>>> PureWindowsPath('b.py').match('*.PY')
True
```

PurePath.relative to(*other)

Compute a version of this path relative to the path represented by *other*. If it's impossible, ValueError is raised:

```
ValueError: '/etc/passwd' is not in the subpath of '/usr' OR
one path is relative and the other absolute.
```

NOTE: This function is part of PurePath and works with strings. It does not check or access the underlying file structure.

```
PurePath.with name(name)
```

Return a new path with the name changed. If the original path doesn't have a name, ValueError is raised:

```
>>>
>>> p = PureWindowsPath('c:/Downloads/pathlib.tar.gz')
>>> p.with_name('setup.py')
PureWindowsPath('c:/Downloads/setup.py')
>>> p = PureWindowsPath('c:/')
>>> p.with_name('setup.py')
Traceback (most recent call last):
   File "<stdin>", line 1, in <module>
   File "/home/antoine/cpython/default/Lib/pathlib.py", line
751, in with_name
   raise ValueError("%r has an empty name" % (self,))
ValueError: PureWindowsPath('c:/') has an empty name
```

PurePath.with stem(stem)

Return a new path with the stem changed. If the original path doesn't have a name, ValueError is raised:

```
>>> p = PureWindowsPath('c:/Downloads/draft.txt')
>>> p.with stem('final')
PureWindowsPath('c:/Downloads/final.txt')
>>> p = PureWindowsPath('c:/Downloads/pathlib.tar.gz')
>>> p.with stem('lib')
PureWindowsPath('c:/Downloads/lib.gz')
>>> p = PureWindowsPath('c:/')
>>> p.with stem('')
Traceback (most recent call last):
 File "<stdin>", line 1, in <module>
 File "/home/antoine/cpython/default/Lib/pathlib.py",
                                                           line
861, in with stem
    return self.with name(stem + self.suffix)
 File "/home/antoine/cpython/default/Lib/pathlib.py",
                                                           line
851, in with name
    raise ValueError("%r has an empty name" % (self,))
ValueError: PureWindowsPath('c:/') has an empty name
```

```
PurePath.with suffix(suffix)
```

Return a new path with the suffix changed. If the original path doesn't have a suffix, the new *suffix* is appended instead. If the *suffix* is an empty string, the original suffix is removed:

```
>>>
>>> p = PureWindowsPath('c:/Downloads/pathlib.tar.gz')
>>> p.with_suffix('.bz2')
PureWindowsPath('c:/Downloads/pathlib.tar.bz2')
>>> p = PureWindowsPath('README')
>>> p.with_suffix('.txt')
PureWindowsPath('README.txt')
>>> p = PureWindowsPath('README.txt')
>>> p.with_suffix('')
PureWindowsPath('README.txt')
```

Concrete paths

Concrete paths are subclasses of the pure path classes. In addition to operations provided by the latter, they also provide methods to do system calls on path objects. There are three ways to instantiate concrete paths:

```
class pathlib.Path(*pathsegments)
```

A subclass of PurePath, this class represents concrete paths of the system's path flavour (instantiating it creates either a PosixPath or a WindowsPath):

```
>>> Path('setup.py')
PosixPath('setup.py')
```

pathsegments is specified similarly to PurePath.

```
class pathlib.PosixPath(*pathsegments)
```

A subclass of Path and PurePosixPath, this class represents concrete non-Windows filesystem paths:

```
>>>
>>> PosixPath('/etc')
PosixPath('/etc')
```

pathsegments is specified similarly to PurePath.

```
class pathlib.WindowsPath(*pathsegments)
```

A subclass of Path and PureWindowsPath, this class represents concrete Windows filesystem paths:

```
>>> WindowsPath('c:/Program Files/')
WindowsPath('c:/Program Files')
```

pathsegments is specified similarly to PurePath.

You can only instantiate the class flavour that corresponds to your system (allowing system calls on non-compatible path flavours could lead to bugs or failures in your application):

```
>>> import os
>>> os.name
'posix'
>>> Path('setup.py')
PosixPath('setup.py')
>>> PosixPath('setup.py')
PosixPath('setup.py')
>>> WindowsPath('setup.py')
Traceback (most recent call last):
   File "<stdin>", line 1, in <module>
   File "pathlib.py", line 798, in __new__
        % (cls.__name__,))
NotImplementedError: cannot instantiate 'WindowsPath' on your system
```

Methods

Concrete paths provide the following methods in addition to pure paths methods. Many of these methods can raise an OSError if a system call fails (for example because the path doesn't exist).

```
Changed in version 3.8: exists(), is_dir(), is_file(), is_mount(), is_symlink(), is _block_device(), is_char_device(), is_fifo(), is_socket() now return False instead of raising an exception for paths that contain characters unrepresentable at the OS level.
```

```
classmethod Path.cwd()
```

Return a new path object representing the current directory (as returned by os.getcwd()):

```
>>> Path.cwd()
PosixPath('/home/antoine/pathlib')
```

classmethod Path.home()

Return a new path object representing the user's home directory (as returned by os.path.expanduser() with ~ construct):

```
>>>
Path.home()
PosixPath('/home/antoine')
```

New in version 3.5.

```
Path.stat()
```

Return a os.stat_result object containing information about this path, like os.stat(). The result is looked up at each call to this method.

```
>>> p = Path('setup.py')
>>> p.stat().st_size
956
>>> p.stat().st_mtime
1327883547.852554
```

Path.chmod(mode)

Change the file mode and permissions, like os.chmod():

```
>>>
>>>
>>>
p = Path('setup.py')
>>> p.stat().st_mode
33277
>>> p.chmod(0o444)
>>> p.stat().st_mode
33060
```

Path.exists()

Whether the path points to an existing file or directory:

```
>>>
>>> Path('.').exists()
True
>>> Path('setup.py').exists()
True
>>> Path('/etc').exists()
True
>>> Path('nonexistentfile').exists()
False
```

Note

If the path points to a symlink, <code>exists()</code> returns whether the symlink *points* to an existing file or directory.

```
Path.expanduser()
```

Return a new path with expanded ~ and ~user constructs, as returned by os.path.expanduser():

```
>>>
>>> p = PosixPath('~/films/Monty Python')
>>> p.expanduser()
PosixPath('/home/eric/films/Monty Python')
```

New in version 3.5.

```
Path.glob(pattern)
```

Glob the given relative *pattern* in the directory represented by this path, yielding all matching files (of any kind):

The "**" pattern means "this directory and all subdirectories, recursively". In other words, it enables recursive globbing:

```
>>>
>>> sorted(Path('.').glob('**/*.py'))
[PosixPath('build/lib/pathlib.py'),
   PosixPath('docs/conf.py'),
   PosixPath('pathlib.py'),
   PosixPath('setup.py'),
   PosixPath('test_pathlib.py')]
```

Note

Using the "**" pattern in large directory trees may consume an inordinate amount of time.

Raises an auditing event pathlib.Path.glob with arguments self, pattern.

Path.group()

Return the name of the group owning the file. KeyError is raised if the file's gid isn't found in the system database.

Return True if the path points to a directory (or a symbolic link pointing to a directory), False if it points to another kind of file.

False is also returned if the path doesn't exist or is a broken symlink; other errors (such as permission errors) are propagated.

Return True if the path points to a regular file (or a symbolic link pointing to a regular file), False if it points to another kind of file.

False is also returned if the path doesn't exist or is a broken symlink; other errors (such as permission errors) are propagated.

Return True if the path is a *mount point*: a point in a file system where a different file system has been mounted. On POSIX, the function checks whether *path*'s parent, path/.., is on a different device than *path*, or whether path/.. and *path* point to the same i-node on the same device — this should detect mount points for all Unix and POSIX variants. Not implemented on Windows.

New in version 3.7.

Return True if the path points to a symbolic link, False otherwise.

False is also returned if the path doesn't exist; other errors (such as permission errors) are propagated.

Return True if the path points to a Unix socket (or a symbolic link pointing to a Unix socket), False if it points to another kind of file.

False is also returned if the path doesn't exist or is a broken symlink; other errors (such as permission errors) are propagated.

Return True if the path points to a FIFO (or a symbolic link pointing to a FIFO), False if it points to another kind of file.

False is also returned if the path doesn't exist or is a broken symlink; other errors (such as permission errors) are propagated.

```
Path.is block device()
```

Return True if the path points to a block device (or a symbolic link pointing to a block device), False if it points to another kind of file.

False is also returned if the path doesn't exist or is a broken symlink; other errors (such as permission errors) are propagated.

```
Path.is char device()
```

Return True if the path points to a character device (or a symbolic link pointing to a character device), False if it points to another kind of file.

False is also returned if the path doesn't exist or is a broken symlink; other errors (such as permission errors) are propagated.

```
Path.iterdir()
```

When the path points to a directory, yield path objects of the directory contents:

```
>>> p = Path('docs')
>>> for child in p.iterdir(): child
...

PosixPath('docs/conf.py')
PosixPath('docs/_templates')
PosixPath('docs/make.bat')
PosixPath('docs/index.rst')
PosixPath('docs/_build')
PosixPath('docs/_static')
PosixPath('docs/_Makefile')
```

The children are yielded in arbitrary order, and the special entries '.' and '..' are not included. If a file is removed from or added to the directory after creating the iterator, whether an path object for that file be included is unspecified.

```
Path.lchmod(mode)
```

Like Path.chmod() but, if the path points to a symbolic link, the symbolic link's mode is changed rather than its target's.

```
Path.lstat()
```

Like Path.stat() but, if the path points to a symbolic link, return the symbolic link's information rather than its target's.

```
Path.mkdir(mode=00777, parents=False, exist ok=False)
```

Create a new directory at this given path. If *mode* is given, it is combined with the process' umask value to determine the file mode and access flags. If the path already exists, FileExistsError is raised.

If *parents* is true, any missing parents of this path are created as needed; they are created with the default permissions without taking *mode* into account (mimicking the POSIX mkdir -p command).

If parents is false (the default), a missing parent raises FileNotFoundError.

If exist_ok is false (the default), FileExistsError is raised if the target directory already exists.

If *exist_ok* is true, FileExistsError exceptions will be ignored (same behavior as the POSIX mkdir -p command), but only if the last path component is not an existing non-directory file.

Changed in version 3.5: The exist_ok parameter was added.

```
Path.open(mode='r', buffering=-
1, encoding=None, errors=None, newline=None)
```

Open the file pointed to by the path, like the built-in open () function does:

```
>>> p = Path('setup.py')
>>> with p.open() as f:
... f.readline()
...
'#!/usr/bin/env python3\n'
```

Path.owner()

Return the name of the user owning the file. KeyError is raised if the file's uid isn't found in the system database.

```
Path.read bytes()
```

Return the binary contents of the pointed-to file as a bytes object:

```
>>>
>>> p = Path('my_binary_file')
>>> p.write_bytes(b'Binary file contents')
20
>>> p.read_bytes()
b'Binary file contents'
```

New in version 3.5.

```
Path.read text(encoding=None, errors=None)
```

Return the decoded contents of the pointed-to file as a string:

```
>>>
>>> p = Path('my_text_file')
>>> p.write_text('Text file contents')
18
>>> p.read_text()
'Text file contents'
```

The file is opened and then closed. The optional parameters have the same meaning as in open().

New in version 3.5.

Path.readlink()

Return the path to which the symbolic link points (as returned by os.readlink()):

```
>>>
>>> p = Path('mylink')
>>> p.symlink_to('setup.py')
>>> p.readlink()
PosixPath('setup.py')
```

New in version 3.9.

Path.rename(target)

Rename this file or directory to the given *target*, and return a new Path instance pointing to *target*. On Unix, if *target* exists and is a file, it will be replaced silently if the user has permission. *target* can be either a string or another path object:

```
>>>
>>> p = Path('foo')
>>> p.open('w').write('some text')
9
>>> target = Path('bar')
>>> p.rename(target)
PosixPath('bar')
>>> target.open().read()
'some text'
```

The target path may be absolute or relative. Relative paths are interpreted relative to the current working directory, *not* the directory of the Path object.

Changed in version 3.8: Added return value, return the new Path instance.

```
Path.replace(target)
```

Rename this file or directory to the given *target*, and return a new Path instance pointing to *target*. If *target* points to an existing file or directory, it will be unconditionally replaced.

The target path may be absolute or relative. Relative paths are interpreted relative to the current working directory, *not* the directory of the Path object.

Changed in version 3.8: Added return value, return the new Path instance.

```
Path.resolve(strict=False)
```

Make the path absolute, resolving any symlinks. A new path object is returned:

```
>>>
>>> p = Path()
>>> p
PosixPath('.')
>>> p.resolve()
PosixPath('/home/antoine/pathlib')
```

"..." components are also eliminated (this is the only method to do so):

```
>>>
>>> p = Path('docs/../setup.py')
>>> p.resolve()
PosixPath('/home/antoine/pathlib/setup.py')
```

If the path doesn't exist and *strict* is True, FileNotFoundError is raised. If *strict* is False, the path is resolved as far as possible and any remainder is appended without checking whether it exists. If an infinite loop is encountered along the resolution path, RuntimeError is raised.

New in version 3.6: The *strict* argument (pre-3.6 behavior is strict).

```
Path.rglob(pattern)
```

This is like calling Path.glob() with "**/" added in front of the given relative pattern:

```
>>>
>>> sorted(Path().rglob("*.py"))
[PosixPath('build/lib/pathlib.py'),
```

```
PosixPath('docs/conf.py'),
PosixPath('pathlib.py'),
PosixPath('setup.py'),
PosixPath('test_pathlib.py')]
```

Raises an auditing event pathlib.Path.rglob with arguments self, pattern.

Path.rmdir()

Remove this directory. The directory must be empty.

```
Path.samefile(other path)
```

Return whether this path points to the same file as *other_path*, which can be either a Path object, or a string. The semantics are similar to os.path.samefile() and os.path.samestat().

An OSError can be raised if either file cannot be accessed for some reason.

```
>>>
>>> p = Path('spam')
>>> q = Path('eggs')
>>> p.samefile(q)
False
>>> p.samefile('spam')
True
```

New in version 3.5.

```
Path.symlink_to(target, target_is_directory=False)

Make this path a symbolic link to target. Under Windows, target_is_directory must be true (default False) if the link's target is a directory. Under POSIX, target_is_directory's value is ignored.
```

```
>>>
>>> p = Path('mylink')
>>> p.symlink_to('setup.py')
>>> p.resolve()
PosixPath('/home/antoine/pathlib/setup.py')
>>> p.stat().st_size
956
>>> p.lstat().st_size
8
```

Note

The order of arguments (link, target) is the reverse of os.symlink()'s.

```
Path.touch(mode=00666, exist ok=True)
```

Create a file at this given path. If *mode* is given, it is combined with the process' umask value to determine the file mode and access flags. If the file already exists, the function succeeds if *exist_ok* is true (and its modification time is updated to the current time), otherwise FileExistsError is raised.

```
Path.unlink(missing ok=False)
```

Remove this file or symbolic link. If the path points to a directory, use Path.rmdir() instead.

If *missing_ok* is false (the default), FileNotFoundError is raised if the path does not exist.

If *missing_ok* is true, FileNotFoundError exceptions will be ignored (same behavior as the POSIX rm -f command).

Changed in version 3.8: The missing_ok parameter was added.

```
Path.link to(target)
```

Create a hard link pointing to a path named target.

New in version 3.8.

```
Path.write bytes(data)
```

Open the file pointed to in bytes mode, write *data* to it, and close the file:

```
>>>
>>>
>>>
p = Path('my_binary_file')
>>> p.write_bytes(b'Binary file contents')
20
>>> p.read_bytes()
b'Binary file contents'
```

An existing file of the same name is overwritten.

New in version 3.5.

```
Path.write text(data, encoding=None, errors=None)
```

Open the file pointed to in text mode, write *data* to it, and close the file:

```
>>>
>>> p = Path('my_text_file')
>>> p.write_text('Text file contents')
```

```
18
>>> p.read_text()
'Text file contents'
```

An existing file of the same name is overwritten. The optional parameters have the same meaning as in open().

New in version 3.5.

Correspondence to tools in the os module

Below is a table mapping various os functions to their corresponding PurePath/Path equivalent.

Note

Although os.path.relpath() and PurePath.relative_to() have some overlapping use-cases, their semantics differ enough to warrant not considering them equivalent.

```
os and os.path
                          pathlib
os.path.abspath()
                          Path.resolve()
os.chmod()
                          Path.chmod()
os.mkdir()
                          Path.mkdir()
os.makedirs()
                          Path.mkdir()
os.rename()
                          Path.rename()
os.replace()
                          Path.replace()
os.rmdir()
                          Path.rmdir()
os.remove(), os.unlink() Path.unlink()
                         Path.cwd()
os.getcwd()
                         Path.exists()
os.path.exists()
                         Path.expanduser() and Path.home()
os.path.expanduser()
                          Path.iterdir()
os.listdir()
os.path.isdir()
                          Path.is dir()
os.path.isfile()
                          Path.is file()
```

| os and os.path | pathlib |
|--------------------|--|
| os.path.islink() | Path.is_symlink() |
| os.link() | Path.link_to() |
| os.symlink() | Path.symlink_to() |
| os.readlink() | Path.readlink() |
| os.stat() | <pre>Path.stat(), Path.owner(), Path.group()</pre> |
| os.path.isabs() | PurePath.is_absolute() |
| os.path.join() | PurePath.joinpath() |
| os.path.basename() | PurePath.name |
| os.path.dirname() | PurePath.parent |
| os.path.samefile() | Path.samefile() |
| os.path.splitext() | PurePath.suffix |
